

How to create a form using Django Forms ?

Last Updated : 16 Aug, 2021

Django forms are an advanced set of HTML forms that can be created using python and support all features of HTML forms in a pythonic way. This post revolves around how to create a basic form using various Form Fields and attributes. Creating a form in Django is completely similar to creating a model, one needs to specify what fields would exist in the form and of what type. For example, to input, a registration form one might need First Name (CharField), Roll Number (IntegerField), and so on.

Creating a form using Django Forms

Illustration of **Django Forms** using an Example. Consider a project named geeksforgeeks having an app named geeks.

Refer to the following articles to check how to create a project and an app in Django.

- [How to Create a Basic Project using MVT in Django?](#)
- [How to Create an App in Django ?](#)

In your geeks app make a new file called forms.py where you would be making all your forms. To create a Django form you need to use [Django Form Class](#). Let's demonstrate it.

In your forms.py Enter the following,

Python3

```
from django import forms

# creating a form
class InputForm(forms.Form):
```

Django Views Model Template Forms Jinja Python SQLite Flask Json Postman Interview Ques

```
    last_name = forms.CharField(max_length = 200)
    roll_number = forms.IntegerField(
        help_text = "Enter 6 digit roll number"
    )
    password = forms.CharField(widget = forms.PasswordInput())
```

Let's explain what exactly is happening, left side denotes the name of the field and to the right of it, you define various functionalities of an input field correspondingly. A field's syntax is denoted as

Syntax :

```
Field_name = forms.FieldType(attributes)
```

Now to render this form into a view, move to views.py and create a home_view as below.

Python3

```
from django.shortcuts import render
from .forms import InputForm

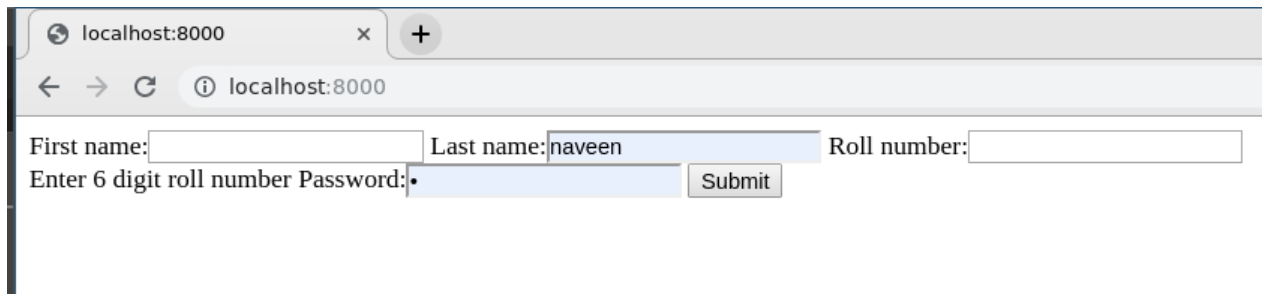

# Create your views here.
def home_view(request):
    context = {}
    context['form'] = InputForm()
    return render(request, "home.html", context)
```

In view, one needs to just create an instance of the form class created above in forms.py. Now let's edit templates > home.html

HTML

```
<form action = "" method = "post">
    {% csrf_token %}
    {{form }}
    <input type="submit" value=Submit">
</form>
```

All set to check if the form is working or not let's visit <http://localhost:8000/>

The form is working properly but visuals are disappointing, Django provides some predefined ways to show forms in a convenient manner. In templates, the following will modify the inputs as,

- `{{ form.as_table }}` will render them as table cells wrapped in `<tr>` tags
- `{{ form.as_p }}` will render them wrapped in `<p>` tags
- `{{ form.as_ul }}` will render them wrapped in `` tags

One can modify these settings also and show fields as he wants using `{{ form.field_name }}` but this may alter the normal process of validation if some field is empty and hence needs extraordinary care. More – [Django Forms](#)

Are you ready to elevate your web development skills from foundational knowledge to advanced expertise? Explore our [Mastering Django Framework - Beginner to Advanced Course](#) on GeeksforGeeks, designed for aspiring developers and experienced programmers. This comprehensive course covers everything you need to know about Django, from the basics to advanced features. Gain practical experience through **hands-on projects** and real-world applications, mastering essential Django principles and techniques. Whether you're just starting or looking to refine your skills, this course will empower you

to build sophisticated web applications efficiently. Ready to enhance your web development journey? Enroll now and unlock your potential with Django!
