

Django Forms

Last Updated : 21 Jul, 2024

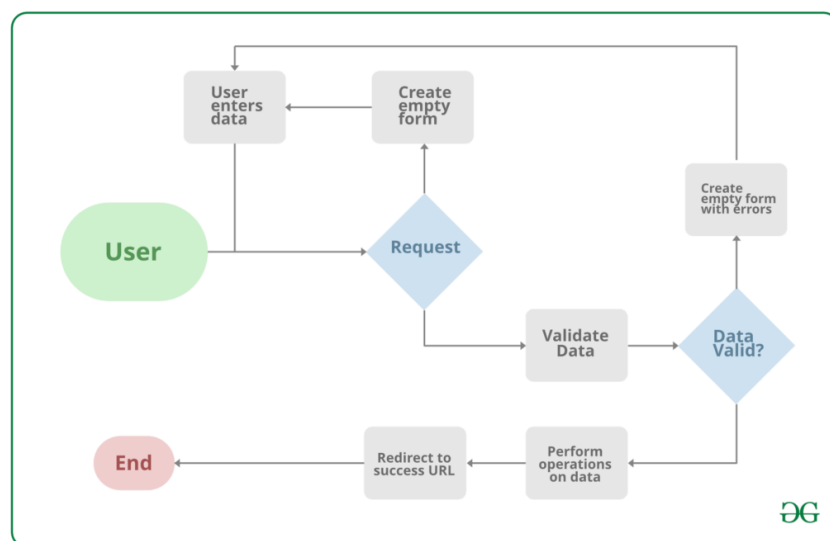

When one creates a **Form** class, the most important part is defining the fields of the form. Each field has custom validation logic, along with a few other hooks. This article revolves around various fields one can use in a form along with various features and techniques concerned with Django Forms.

Django Forms

Forms are used for taking input from the user in some manner and using that information for logical operations on databases. For example, Registering a user by taking input such as his name, email, password, etc.

Django maps the fields defined in Django forms into HTML input fields. Django handles three distinct parts of the work involved in forms:

- Preparing and restructuring data to make it ready for rendering.
- Creating HTML forms for the data.
- Receiving and processing submitted forms and data from the client.

Note that all types of work done by forms in Django can be done with advanced HTML stuff, but Django makes it easier and efficient especially the

validation part. Once you get hold of forms in Django you will just forget about HTML forms.

Syntax : Django Fields work like Django Model Fields and have the syntax:

```
field_name = forms.FieldType(**options)
```

Example

Python

```
1 from django import forms
2
3 # creating a form
4 class GeeksForm(forms.Form):
5     title = forms.CharField()
6     description = forms.CharField()
```

To use Forms in Django, one needs to have a project and an app working in it. After you start an app you can create a form in app/forms.py. Before starting to use a form let's check how to start a project and implement Django Forms.

Refer to the following articles to check how to create a project and an app in Django.

- [How to Create a Basic Project using MVT in Django?](#)
- [How to Create an App in Django ?](#)

Creating Forms in Django

Creating a form in Django is completely similar to creating a model, one needs to specify what fields would exist in the form and of what type. For example, to input, a registration form one might need First Name (CharField), Roll Number (IntegerField), and so on.

Syntax:

```
from django import forms

class FormName(forms.Form):
    # each field would be mapped as an input field in HTML
    field_name = forms.Field(**options)
```

To create a form, in geeks/forms.py Enter the code,

Python

```
1 # import the standard Django Forms
2 # from built-in library
3 from django import forms
4
5 # creating a form
6 class InputForm(forms.Form):
7
8     first_name = forms.CharField(max_length = 200)
9     last_name = forms.CharField(max_length = 200)
10    roll_number = forms.IntegerField(
11        help_text = "Enter 6 digit roll number"
12    )
13    password = forms.CharField(widget =
    forms.PasswordInput())
```

To know more about how to create a Form using Django forms, visit [How to create a form using Django Forms ?](#).

Render Django Forms

Django form fields have several built-in methods to ease the work of the developer but sometimes one needs to implement things manually for customizing User Interface(UI). A form comes with 3 in-built methods that can be used to render Django form fields.

- `{{ form.as_table }}` will render them as table cells wrapped in `<tr>` tags
- `{{ form.as_p }}` will render them wrapped in `<p>` tags
- `{{ form.as_ul }}` will render them wrapped in `` tags

To render this form into a view, move to `views.py` and create a `home_view` as below.

Python

```
1 from django.shortcuts import render
2 from .forms import InputForm
3
4 # Create your views here.
5 def home_view(request):
6     context = {}
7     context['form'] = InputForm()
8     return render(request, "home.html", context)
```

In view, one needs to just create an instance of the form class created above in forms.py. Now let's edit templates > home.html

html

```
1 <form action = "" method = "post">
2     {% csrf_token %}
3     {{form }}
4     <input type="submit" value=Submit">
5 </form>
```

Now, visit <http://localhost:8000/>

localhost:8000 x +

localhost:8000

First name: Last name: Roll number:

Enter 6 digit roll number Password:

To check how to use the data rendered by Django Forms visit [Render Django Form Fields](#)

Create Django Form from Models

Django ModelForm is a class that is used to directly convert a model into a Django form. If you're building a database-driven app, chances are you'll have

forms that map closely to Django models. Now when we have our project ready, create a model in `geeks/models.py`,

Python

```
1  # import the standard Django Model
2  # from built-in library
3  from django.db import models
4
5  # declare a new model with a name "GeeksModel"
6  class GeeksModel(models.Model):
7      # fields of the model
8      title = models.CharField(max_length = 200)
9      description = models.TextField()
10     last_modified = models.DateTimeField(auto_now_add =
    True)
11     img = models.ImageField(upload_to = "images/")
12
13     # renames the instances of the model
14     # with their title name
15     def __str__(self):
16         return self.title
```

To create a form directly for this model, dive into `geeks/forms.py` and Enter the following code:

Python

```
1 # import form class from django
2 from django import forms
3
4 # import GeeksModel from models.py
5 from .models import GeeksModel
6
7 # create a ModelForm
8 class GeeksForm(forms.ModelForm):
9     # specify the name of model to use
10     class Meta:
11         model = GeeksModel
12         fields = "__all__"
```

Now visit <http://127.0.0.1:8000/>,

Django Forms Data Types and Fields List

The most important part of a form and the only required part is the list of fields it defines. Fields are specified by class attributes. Here is a list of all Form Field types used in Django

Name	Class	HTML Input
BooleanField	class BooleanField(**kwargs)	CheckboxInput
CharField	class CharField(**kwargs)	TextInput
ChoiceField	class ChoiceField(**kwargs)	Select
TypedChoiceField	class TypedChoiceField(**kwargs)	Select
DateField	class DateField(**kwargs)	DateInput
DateTimeField	class DateTimeField(**kwargs)	DateTimeInput
DecimalField	class DecimalField(**kwargs)	NumberInput when Field.localize i

Name	Class	HTML Input
		False, else TextInput
<u>DurationField</u>	class DurationField(**kwargs)	TextInput
<u>EmailField</u>	class EmailField(**kwargs)	EmailInput
<u>FileField</u>	class FileField(**kwargs)	ClearableFileInp
<u>FilePathField</u>	class FilePathField(**kwargs)	Select
<u>FloatField</u>	class FloatField(**kwargs)	NumberInput when Field.localize i False, else TextInput
<u>ImageField</u>	class ImageField(**kwargs)	ClearableFileInp
<u>IntegerField</u>	class IntegerField(**kwargs)	NumberInput when Field.localize i False, else TextInput
<u>GenericIPAddressField</u>	class GenericIPAddressField(**kwargs)	TextInput
<u>MultipleChoiceField</u>	class MultipleChoiceField(**kwargs)	SelectMultiple
<u>TypedMultipleChoiceField</u>	class TypedMultipleChoiceField(**kwargs)	SelectMultiple
<u>NullBooleanField</u>	class NullBooleanField(**kwargs)	NullBooleanSel

Name	Class	HTML Input
RegexField	class RegexField(**kwargs)	TextInput
SlugField	class SlugField(**kwargs)	TextInput
TimeField	class TimeField(**kwargs)	TimeInput
URLField	class URLField(**kwargs)	URLInput
UUIDField	class UUIDField(**kwargs)	TextInput

Core Field Arguments

Core Field arguments are the arguments given to each field for applying some constraint or imparting a particular characteristic to a particular Field. For example, adding an argument `required = False` to `CharField` will enable it to be left blank by the user. Each Field class constructor takes at least these arguments. Some Field classes take additional, field-specific arguments, but the following should always be accepted:

Field Options	Description
required	By default, each Field class assumes the value is required, so to make it not required you need to set <code>required=False</code>
label	The label argument lets you specify the “human-friendly” label for this field. This is used when the Field is displayed in a Form.
label_suffix	The <code>label_suffix</code> argument lets you override the form’s label_suffix on a per-field basis.
widget	The widget argument lets you specify a Widget class to use when rendering this Field. See Widgets for more information.

Field Options	Description
help_text	The help_text argument lets you specify descriptive text for this Field. If you provide help_text, it will be displayed next to the Field when the Field is rendered by one of the convenience Form methods.
error_messages	The error_messages argument lets you override the default messages that the field will raise. Pass in a dictionary with keys matching the error messages you want to override.
validators	The validators argument lets you provide a list of validation functions for this field.
localize	The localize argument enables the localization of form data input, as well as the rendered output.
disabled	The disabled boolean argument, when set to True, disables a form field using the disabled HTML attribute so that it won't be editable by users.

Are you ready to elevate your web development skills from foundational knowledge to advanced expertise? Explore our [Mastering Django Framework - Beginner to Advanced Course](#) on GeeksforGeeks, designed for aspiring developers and experienced programmers. This comprehensive course covers everything you need to know about Django, from the basics to advanced features. Gain practical experience through **hands-on projects** and real-world applications, mastering essential Django principles and techniques. Whether you're just starting or looking to refine your skills, this course will empower you to build sophisticated web applications efficiently. Ready to enhance your web development journey? Enroll now and unlock your potential with Django!
