

# Render Django Form Fields Manually

Last Updated : 22 Jul, 2021

Django form fields have several built-in methods to ease the work of the developer but sometimes one needs to implement things manually for customizing User Interface(UI). We have already covered on [How to create and use a form in Django?](#). A form comes with 3 in-built methods that can be used to render Django form fields.

- `{{ form.as_table }}` will render them as table cells wrapped in `<tr>` tags
- `{{ form.as_p }}` will render them wrapped in `<p>` tags
- `{{ form.as_ul }}` will render them wrapped in `<li>` tags

These render the form automatically but if you want to create a beautiful form with some CSS effects, you need to render the form fields manually. This article revolves around how to render the form fields manually.

## Rendering Form fields manually

Illustration of **Rendering Django Forms Manually** using an Example. Consider a project named geeksforgeeks having an app named geeks.

*Refer to the following articles to check how to create a project and an app in Django.*

- [How to Create a Basic Project using MVT in Django?](#)
- [How to Create an App in Django ?](#)

In your geeks app make a new file called forms.py where you would be making all your forms. To create a Django form you need to use [Django Form Class](#).

Let's demonstrate how,

In your forms.py Enter the following,

---

## Python3

```
from django import forms

# creating a form
class InputForm(forms.Form):

    first_name = forms.CharField(max_length = 200)
    last_name = forms.CharField(max_length = 200)
    roll_number = forms.IntegerField(
        help_text = "Enter 6 digit roll number"
    )
    password = forms.CharField(widget = forms.PasswordInput())
```

Let's explain what exactly is happening, left side denotes the name of the field and to right of it, you define various functionalities of an input field correspondingly. A field's syntax is denoted as

**Syntax :**

```
Field_name = forms.FieldType(attributes)
```

Now to render this form into a view, move to views.py and create a home\_view as below.

---

## Python3

```
from django.shortcuts import render
from .forms import InputForm
```

```
# Create your views here.  
def home_view(request):  
    context = {}  
    context['form'] = InputForm()  
    return render(request, "home.html", context)
```

In view one needs to just create an instance of the form class created above in forms.py.

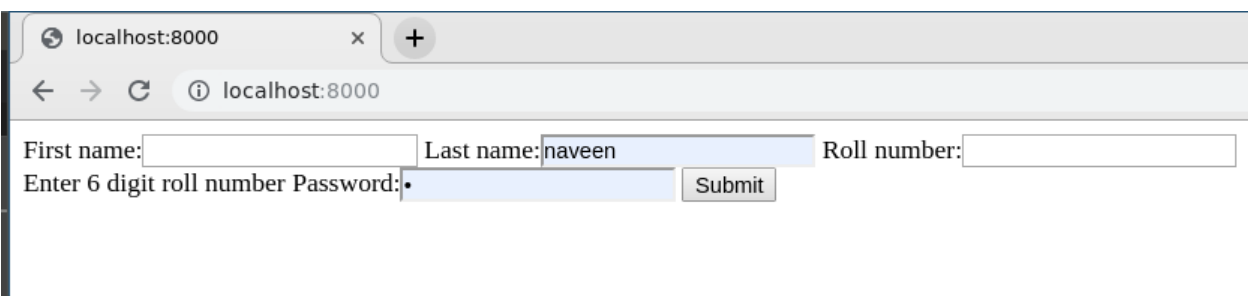

Now let's edit templates > home.html

---

## html

```
<form action = "" method = "post">  
    {% csrf_token %}  
    {{form }}  
    <input type="submit" value=Submit">  
</form>
```

All set to check if form is working or not let's visit <http://localhost:8000/>

localhost:8000

First name:  Last name: naveen Roll number:

Enter 6 digit roll number Password:

Form is working properly but visuals are disappointing, We can render these fields manually to improve some visual stuff. Each field is available as an attribute of the form using `{{ form.name_of_field }}`, and in a Django template, will be rendered appropriately. For example:

```
{{ form.non_field_errors }}  
<div class="fieldWrapper">  
    {{ form.subject.errors }}  
    <label for="{{ form.subject.id_for_label }}">Email subject:</label>  
    {{ form.subject }}  
</div>
```

Let's modify our form to look pretty impressive,

---

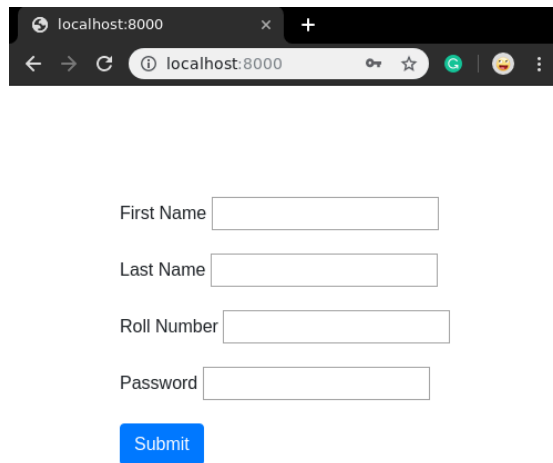

## html

```
<html>  
  
<head>  
    <link  
        rel="stylesheet"  
        href="https://stackpath.bootstrapcdn.com/bootstrap/4.4.1/css/bootstrap.min.cs:  
    <style>  
        .i-am-centered {  
            margin: auto;  
            max-width: 300px;  
            padding-top: 20%;  
        }  
    </style>  
</head>  
  
<body>  
    <div class="i-am-centered">  
        <form method="POST">  
            {% csrf_token %}  
            <div class="form-group">  
                <label>First Name </label>  
                {{ form.first_name }}  
            </div>  
            <div class="form-group">  
                <label>Last Name </label>  
                {{ form.last_name }}  
            </div>  
            <div class="form-group">  
                <label>Roll Number</label>  
                {{ form.roll_number }}  
            </div>  
            <div class="form-group">
```

```
<label>Password</label>
{{ form.password }}
</div>
<button type="submit" class="btn btn-primary">Submit</button>
</form>
</div>
</body>

</html>
```

Now visit <http://localhost:8000/> and check modified form.

A screenshot of a web browser window with the address bar showing 'localhost:8000'. The browser has a dark theme. Below the address bar, there is a form with four input fields stacked vertically. The first field is labeled 'First Name', the second 'Last Name', the third 'Roll Number', and the fourth 'Password'. Below these fields is a blue button with the text 'Submit' in white.

These were just some basic modifications using Bootstrap. One can customize it to an advanced level using various CSS tricks and methods.

## {{ field }} attributes

- **{{ field.label }}**  
The label of the field, e.g. Email address.
- **{{ field.label\_tag }}**  
The field's label wrapped in the appropriate HTML tag. This includes the form's label\_suffix. For example, the default label\_suffix is a colon:

```
<label for="id_email">Email address:</label>
```

- **{{ field.id\_for\_label }}**

The ID that will be used for this field (id\_email in the example above). If you are constructing the label manually, you may want to use this in place of label\_tag. It's also useful, for example, if you have some inline JavaScript and want to avoid hardcoding the field's ID.

- **{{ field.value }}**

The value of the field. e.g someone@example.com.

- **{{ field.html\_name }}**

The name of the field that will be used in the input element's name field. This takes the form prefix into account, if it has been set.

- **{{ field.help\_text }}**

Any help text that has been associated with the field.

- **{{ field.errors }}**

Outputs a <ul class="errorlist"> containing any validation errors corresponding to this field. You can customize the presentation of the errors with a {% for error in field.errors %} loop. In this case, each object in the loop is a string containing the error message.

- **{{ field.is\_hidden }}**

This attribute is True if the form field is a hidden field and False otherwise. It's not particularly useful as a template variable, but could be useful in conditional tests such as:

```
{% if field.is_hidden %}
    {# Do something special #}
{% endif %}
```

- **{{ field.field }}**

The Field instance from the form class that this BoundField wraps. You can use it to access Field attributes, e.g. {{ char\_field.field.max\_length }}
