

Python Numpy

Last Updated : 15 Jul, 2024

Numpy is a general-purpose array-processing package. It provides a high-performance multidimensional array object, and tools for working with these arrays. It is the fundamental package for scientific computing with Python.

Besides its obvious scientific uses, Numpy can also be used as an efficient multi-dimensional container of generic data.

Arrays in Numpy

Array in Numpy is a table of elements (usually numbers), all of the same type, indexed by a tuple of positive integers. In Numpy, number of dimensions of the array is called rank of the array. A tuple of integers giving the size of the array along each dimension is known as shape of the array. An array class in Numpy is called as **ndarray**. Elements in Numpy arrays are accessed by using square brackets and can be initialized by using nested Python Lists.

Creating a Numpy Array

Arrays in Numpy can be created by multiple ways, with various number of Ranks, defining the size of the Array. Arrays can also be created with the use of various data types such as lists, tuples, etc. The type of the resultant array is deduced from the type of the elements in the sequences.

Note: Type of array can be explicitly defined while creating the array.

Python

```
1 # Python program for
2 # Creation of Arrays
3 import numpy as np
4
5 # Creating a rank 1 Array
6 arr = np.array([1, 2, 3])
7 print("Array with Rank 1: \n",arr)
8
```

```
9  # Creating a rank 2 Array
10 arr = np.array([[1, 2, 3],
11                 [4, 5, 6]])
12 print("Array with Rank 2: \n", arr)
13
14 # Creating an array from tuple
15 arr = np.array((1, 3, 2))
16 print("\nArray created using "
17       "passed tuple:\n", arr)
```

Output

Array with Rank 1:

```
[1 2 3]
```

Array with Rank 2:

```
[[1 2 3]
 [4 5 6]]
```

Array created using passed tuple:

```
[1 3 2]
```

Accessing the array Index

In a numpy array, indexing or accessing the array index can be done in multiple ways. To print a range of an array, slicing is done. Slicing of an array is defining a range in a new array which is used to print a range of elements from the original array. Since, sliced array holds a range of elements of the original array, modifying content with the help of sliced array modifies the original array content.

Python

```
1  # Python program to demonstrate
2  # indexing in numpy array
3  import numpy as np
4
5  # Initial Array
6  arr = np.array([[-1, 2, 0, 4],
7                 [4, -0.5, 6, 0],
8                 [2.6, 0, 7, 8],
```

```

9             [3, -7, 4, 2.0]])
10 print("Initial Array: ")
11 print(arr)
12
13 # Printing a range of Array
14 # with the use of slicing method
15 sliced_arr = arr[:2, ::2]
16 print ("Array with first 2 rows and"
17        " alternate columns(0 and 2):\n", sliced_arr)
18
19 # Printing elements at
20 # specific Indices
21 Index_arr = arr[[1, 1, 0, 3],
22                 [3, 2, 1, 0]]
23 print ("\nElements at indices (1, 3), "
24        "(1, 2), (0, 1), (3, 0):\n", Index_arr)

```

Output

Initial Array:

```

[[-1.  2.  0.  4. ]
 [ 4. -0.5 6.  0. ]
 [ 2.6  0.  7.  8. ]
 [ 3. -7.  4.  2. ]]

```

Array with first 2 rows and alternate columns(0 and 2):

```

[[-1.  0.]
 [ 4.  6.]]

```

Elements a...

Basic Array Operations

In numpy, arrays allow a wide range of operations which can be performed on a particular array or a combination of Arrays. These operation include some basic Mathematical operation as well as Unary and Binary operations.

Python

```

1 # Python program to demonstrate
2 # basic operations on single array
3 import numpy as np

```

```
4
5 # Defining Array 1
6 a = np.array([[1, 2],
7               [3, 4]])
8
9 # Defining Array 2
10 b = np.array([[4, 3],
11               [2, 1]])
12
13 # Adding 1 to every element
14 print ("Adding 1 to every element:", a + 1)
15
16 # Subtracting 2 from each element
17 print ("\nSubtracting 2 from each element:", b - 2)
18
19 # sum of array elements
20 # Performing Unary operations
21 print ("\nSum of all array "
22        "elements: ", a.sum())
23
24 # Adding two arrays
25 # Performing Binary operations
26 print ("\nArray sum:\n", a + b)
```

Output

```
Adding 1 to every element: [[2 3]
[4 5]]
```

```
Subtracting 2 from each element: [[ 2  1]
[ 0 -1]]
```

```
Sum of all array elements: 10
```

```
Array sum:
[[5 5]
[5 5]]
```

Data Types in Numpy

Every Numpy array is a table of elements (usually numbers), all of the same type, indexed by a tuple of positive integers. Every ndarray has an associated data type (dtype) object. This data type object (dtype) provides information about the layout of the array. The values of an ndarray are stored in a buffer which can be thought of as a contiguous block of memory bytes which can be interpreted by the dtype object. Numpy provides a large set of numeric datatypes that can be used to construct arrays. At the time of Array creation, Numpy tries to guess a datatype, but functions that construct arrays usually also include an optional argument to explicitly specify the datatype.

Constructing a Datatype Object

In Numpy, datatypes of Arrays need not to be defined unless a specific datatype is required. Numpy tries to guess the datatype for Arrays which are not predefined in the constructor function.

Python

```
1  # Python Program to create
2  # a data type object
3  import numpy as np
4
5  # Integer datatype
6  # guessed by Numpy
7  x = np.array([1, 2])
8  print("Integer Datatype: ")
9  print(x.dtype)
10
11 # Float datatype
12 # guessed by Numpy
13 x = np.array([1.0, 2.0])
14 print("\nFloat Datatype: ")
15 print(x.dtype)
16
17 # Forced Datatype
18 x = np.array([1, 2], dtype = np.int64)
```

```
19 print("\nForcing a Datatype: ")
20 print(x.dtype)
```

Output

Integer Datatype:

int64

Float Datatype:

float64

Forcing a Datatype:

int64

Math Operations on DataType array

In Numpy arrays, basic mathematical operations are performed element-wise on the array. These operations are applied both as operator overloads and as functions. Many useful functions are provided in Numpy for performing computations on Arrays such as **sum**: for addition of Array elements, **T**: for Transpose of elements, etc.

Python

```
1 # Python Program to create
2 # a data type object
3 import numpy as np
4
5 # First Array
6 arr1 = np.array([[4, 7], [2, 6]],
7                 dtype = np.float64)
8
9 # Second Array
10 arr2 = np.array([[3, 6], [2, 8]],
11                 dtype = np.float64)
12
13 # Addition of two Arrays
14 Sum = np.add(arr1, arr2)
15 print("Addition of Two Arrays: ")
16 print(Sum)
```

```
17
18 # Addition of all Array elements
19 # using predefined sum method
20 Sum1 = np.sum(arr1)
21 print("\nAddition of Array elements: ")
22 print(Sum1)
23
24 # Square root of Array
25 Sqrt = np.sqrt(arr1)
26 print("\nSquare root of Array1 elements: ")
27 print(Sqrt)
28
29 # Transpose of Array
30 # using In-built function 'T'
31 Trans_arr = arr1.T
32 print("\nTranspose of Array: ")
33 print(Trans_arr)
```

Output

Addition of Two Arrays:

```
[[ 7. 13.]
 [ 4. 14.]]
```

Addition of Array elements:

```
19.0
```

Square root of Array1 elements:

```
[[2.          2.64575131]
 [1.41421356  2.44948974]]
```

Transpose of Array:

```
[[4.  2.]
 ...
```
